

## C3 · Potential Analysis

*The dossier of one object — written in the language of the client's own strategy.*

### What this screen is for

Each object opens on its own generated page. This is where our technology becomes visible: the analysis reads like it was written for this specific investor, because the template adapts to his strategy. A Fix & Flip investor and a Buy & Hold investor see the same object explained through different logic. The heart of every version is the same idea: the weaknesses of the object, shown honestly, and then turned into upside. Every dossier page also carries an intelligent link, so the office can see which objects the client spends time on — quiet evidence that the technology creates value.

### What is on the screen

|                          |                                                                                                                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Identity strip</b>    | Object ID, asset type, district-level location, ticket range, and the score. Exact address stays hidden until the mandate.                                                                                                                    |
| <b>Strategy fit</b>      | One short block explaining why this object matches the client's thesis — in his vocabulary. There is a separate template per strategy (Fix & Flip, Buy & Hold, Value Add, ...), so this section always sounds like the client's own thinking. |
| <b>Weakness → upside</b> | The core of the dossier. Three to five pairs: what is wrong with the object, and what that weakness is worth to this investor. Outdated building → renovation upside. Rent below market → rent growth. Underused land → densification.        |
| <b>The numbers</b>       | Value today, value after improvement, upside range. Three numbers, large and honest.                                                                                                                                                          |
| <b>Risks</b>             | Only the risks that matter for this object, each with a simple severity. No standard risk catalogue.                                                                                                                                          |
| <b>Actions</b>           | Select (adds the object to the client's selection — like a cart) and Reject. 'Save for later' and 'Request deeper evaluation' exist as quiet secondary links.                                                                                 |

### How the user moves through it

- 1 The client opens an object from the catalogue.
- 2 He reads why it fits his strategy, then how its weaknesses become his upside.
- 3 He checks the three numbers and the real risks.
- 4 He selects, rejects, or saves it — and goes back to the list for the next one.

### Notes for the design

- This page is a document, not a dashboard. It should read top to bottom like a well-made dossier.
- The weakness → upside logic is the signature of the product — give it the most beautiful treatment on the page.
- One dossier design, many strategy templates: the layout stays identical, only the argument changes.
- Select and Reject are the only strong buttons. Everything else is a link.
